Open registry and tooling for agents and multi-agent flows

agents-repo.org

What this org is

- An **open registry** for agents and multi-agent flows
- Distributed to **install targets** (AI coding tools)
- Specs and package source live in **registry**
- Webapp and CLI fetch the catalog through **registry-proxy** by default

Not “Copilot agents only.” Product voice: install targets and AI coding tools.

Install targets

Marketing list order:

1. GitHub Copilot
2. Cursor
3. Claude Code
4. OpenAI Codex

Normative IDs live in the registry `install-targets` spec. Display names live in `org docs/marketing-vocabulary.md`.

Repositories

Repo	Role
registry	Specs, <code>packages/</code> catalog, ZIP artifacts
registry-proxy	Cached read-only Worker for registry files
webapp	Browse / search / download → agents-repo.org
cli	<code>npx agents-repo</code> install and project config
.github	Org profile, CONTRIBUTING, this convention

How the pieces fit

1. Contributors publish packages to **registry** via GitHub pull request
2. **semantic-release** tags catalog snapshots (for example `v2.x`)
3. **webapp** and **cli** resolve a catalog ref
4. Default fetch URL is **registry-proxy** (overridable in env / config)
5. Public site is **webapp** deployed to GitHub Pages

Publish a package (high level)

- Fork **agents-repo/registry** (external contributors)
- Add source under `packages/<namespace>/<package-id>/`
- Validate, build ZIPs, update catalog metadata
- Draft PR → human marks ready → squash `feat(package):` or `fix(package):`

Runtime logic stays **out of** the registry.

Browse vs install

Webapp (agents-repo.org)

- `packages/index.json` then package `detail.json`

CLI (`npx agents-repo`)

- `packages/index.json` then `versions/manifest.json`
- Version `metadata.json` and `<version>-<target-id>.zip`

Same catalog, different paths after the index.

Default catalog URL

Production webapp and org `agents.json` :

```
https://registry.agents-repo.org?ref=v2.x
```

Override with webapp `VITE_*` settings, CLI `agents.json` / env
(`AGENTS_REPO_REGISTRY_URL`), or a direct GitHub source in development.

Install targets on disk

The CLI extracts each ZIP into IDE-specific paths:

- GitHub Copilot → `.github/agents`
- Cursor → `.cursor/skills` and rules
- Claude Code → `.claude/agents`
- OpenAI Codex → `.agents/skills`

IDs are normative in registry specs; do not invent new ones in slides.

Public site

- **agents-repo.org** — user guides, package browser, repo pages
- Built from **webapp**
- Pages target **agents-repo.github.io** (not a development repo)

Org docs also live in this `.github` repository
(`docs/ecosystem.md` , `CONTRIBUTING.md`).

Specs live in registry

Normative rules (package format, agent/flow files, manifests, versioning) are in `agents-repo/registry` `specs/` .

This org repo holds **policies and orientation**, not those contracts.

Deeper decks

Topic	Repository
Package creation	registry
Webapp infrastructure	webapp
CLI usage	cli
Proxy architecture	registry-proxy

Each repo keeps source + PDF under `docs/slides/` .
